A: IPProc is one such utility. The URL is here. You need to run the command line "ipproc" and then the specific program from your program folder. Genomic heterogeneity of a 14 kb insertion in the promoter region of the beta-fibrinogen gene. A family in which the mother and daughter have a haematological disorder affecting plasminogen, fibrinogen and Factor V, was investigated for a possible genetic cause. Haemostatic factors and their precursors are influenced by a number of regulatory genes and modifying factors. In our patient, the plasminogen was deficient, the Factor V defective and the fibrinogen defective. At first, an unknown mutation in the promotor region of the fibrinogen gene was postulated, however, an inversion of the patient's chromosome 17 was found. The breakpoint of the inversion was localised to a 14 kb insertion within the promoter region of the fibrinogen gene. By sequencing of the inserted segment, the breakpoint was mapped within a part of the thrombomodulin gene. The insertion was composed of two parts: one part inserted into the thrombomodulin gene, the other part was deleted within the gene for the glycosyl-phosphatidylinositol-anchored protein (CDw29), which is present on the plasma membrane of monocytes. These findings could indicate that the thrombomodulin gene is not only a fibrinogen, but is also part of a glycoprotein complex expressed by monocytes. Narrow genetic diversity in a tropical southernmost bat species, *Artibeus jamaicensis*, but population stability despite anthropogenic change. The genus *Artibeus* comprises morphologically similar taxa that are broadly defined as they share a fairly constant, pigmentation-based color pattern. They are common in most Neotropical regions and exhibit a high degree of phenotypic plasticity, which is probably related to their behavioral plasticity. Genetic diversity is expected to be low in these species
